# 1 Momentum Loss of Distribution Function in Propagation

In general curvilinear coordinates, for macroscopic values i.e.,  $\rho, \rho \vec{u}$  exist the loss due to the curvature and uniform properties. And this paper shows the value below:

$$\delta N_\alpha(\vec{q}, t) \equiv N_\alpha(q, t) - N_\alpha^*(q - 1, t - 1) \quad (1.1)$$

where  $q$  is the non-dimension position, and the origin form of it is  $\vec{q} = (q_1, q_2, q_3)$ . The value  $N^*$  represents post-collision distribution function. We can review the Lattice Boltzman Equation-BGK (LBGK) and see the position of the value in the equation.

$$N_\alpha(q + 1, t + 1) = N_\alpha(q, t) + \Omega_\alpha + \delta N_\alpha(q, t) \quad (1.2)$$

For general orthogonal curvilinear coordinate in three dimensions, we have the loss of the momentum and loss of the density is 0, so we have the relation:

$$\begin{aligned} \sum_{\alpha=0}^{q-1} \delta N_\alpha(q, t) &= \sum_{\alpha=0}^{q-1} N_\alpha(q, t) - N_\alpha^*(q - 1, t - 1) \\ &= \sum_{\alpha=0}^{q-1} N_\alpha(q, t) - \sum_{\alpha=0}^{q-1} N_\alpha^*(q - 1, t - 1) = 0 \end{aligned} \quad (1.3)$$

But for momentum loss, we have to take the physical meaning as "inertial force" at first. The value in equation (1.1) is modified term in the process of the streaming step. The reason why we have to consider the loss is to achieve momentum conservation through adding the term.

**Definition 1.1.**

$$\vec{\Theta}_i^j(\vec{q}, t) = \left[ \vec{g}_i(\vec{q}, t) - \vec{g}_i(\vec{q} - \vec{c}_i \Delta t, t) \right] \cdot \vec{g}^j \quad (1.4)$$

we call the value is "non-dimension change of curvature tangent vector", where  $\vec{g}^j$  can be defined as below:

$$\vec{g}^1 = \frac{\vec{g}_2 \times \vec{g}_3}{(\vec{g}_2 \times \vec{g}_3) \cdot \vec{g}_1} \quad (1.5)$$

Substitute the vector in equation (1.4)

$$\vec{\Theta}_i^j(\vec{q}, t) = \left[ \vec{g}_i(\vec{q}, t) - \vec{g}_i(\vec{q} - \vec{c}_i \Delta t, t) \right] \cdot \frac{\vec{g}_2 \times \vec{g}_3}{(\vec{g}_2 \times \vec{g}_3) \cdot \vec{g}_1} \quad (1.6)$$

**Definition 1.2.**

$$\begin{aligned} \vec{M}_{\text{Loss}}(q, t) &\equiv \sum_{\alpha=1}^q [N_\alpha(q, t) \vec{e}_\alpha(q, t) - N_\alpha^*(q - 1, t - 1) \vec{e}_\alpha(q - 1, t - 1)] \\ \vec{M}_{\text{Loss}}(q + 1, t + 1) &\equiv \sum_{\alpha=1}^q [N_\alpha(q + 1, t + 1) \vec{e}_\alpha(q + 1, t + 1) - N_\alpha^*(q, t) \vec{e}_\alpha(q, t)] \end{aligned} \quad (1.7)$$

For curvilinear coordinates, the loss of momentum always exists in the streaming step. The basic

reason of the loss of macroscopic value is:

$$N_\alpha(\vec{q}, t) \neq N_\alpha^*(\vec{q} - \vec{e}_\alpha \Delta t, t - 1) \quad (1.8)$$

But this paper defines two values about inner and outer at the point  $(q, t)$  as shown:

**Definition 1.3.**

$$\begin{aligned} \mathcal{J}(q) \bar{\chi}^{\text{in}}(q, t) &\equiv - \sum_{\alpha=1}^q N_\alpha(q, t) (\vec{e}_\alpha(q, t) - \vec{e}_\alpha(q - 1, t - 1)) \\ \mathcal{J}(q) \bar{\chi}^{\text{out}}(q, t) &\equiv - \sum_{\alpha=1}^q (\vec{e}_\alpha(q + 1, t + 1) - \vec{e}_\alpha(q, t)) N_\alpha^*(q, t) \end{aligned} \quad (1.9)$$

where, for the discrete particle velocity set

$$\vec{e}_\alpha(q, t) = \vec{c}_\alpha(q, t) = \sum_{i=1}^3 (\vec{c}_\alpha \cdot \vec{g}_i) \frac{\Delta x}{\Delta t} = c_\alpha^i \vec{g}_i \frac{\Delta x}{\Delta t} \quad (1.10)$$

In this paper, the momentum loss and its definition can be separated into two directions about the point  $(q, t)$ , i.e., inner and outer. The difference from the true "momentum loss of the propagation" is: take post-collision distribution function at  $(q - 1, t - 1)$ :  $N_\alpha^*(q - 1, t - 1)$ ; take the pre-collision function at  $(q, t)$ :  $N_\alpha(q, t)$  for curvilinear normalized discrete particle velocity set:  $\vec{e}_\alpha(q - 1, t - 1)$  and  $\vec{e}_\alpha(q, t)$ . The author take the constraint for momentum in the process of propagation as shown :

$$\begin{aligned} \sum_{\alpha=1}^q \vec{e}_\alpha(q, t) \delta N_\alpha(q, t) &= \sum_{\alpha=1}^q \vec{e}_\alpha(q, t) N_\alpha(q, t) - \sum_{\alpha=1}^q \vec{e}_\alpha(q, t) N_\alpha^*(q - 1, t - 1) \\ &= \mathcal{J} \cdot \frac{\bar{\chi}^{\text{in}}(q, t) + \bar{\chi}^{\text{out}}(q, t)}{2} \end{aligned} \quad (1.11)$$

$$\begin{aligned} \sum_{\alpha=1}^q \vec{e}_\alpha(q, t) \delta N_\alpha(q, t) &= \\ \mathcal{J} \cdot \frac{- \sum_{\alpha=1}^q N_\alpha(q, t) (\vec{e}_\alpha(q, t) - \vec{e}_\alpha(q - 1, t - 1)) - \sum_{\alpha=1}^q N_\alpha^*(q, t) (\vec{e}_\alpha(q + 1, t + 1) - \vec{e}_\alpha(q, t))}{2} \end{aligned} \quad (1.12)$$

**Definition 1.4.** Velocity-space discretized force field – specific case in curvilinear coordinates

$$F^i(q, t) = \frac{\bar{\chi}^{\text{in}}(q, t) + \bar{\chi}^{\text{out}}(q, t)}{2} \cdot \vec{g}^i(q, t) \quad (1.13)$$

The macroscopic force is discretized in particle-velocity space, and this represents an inertial force produced in a curvilinear-coordinate computational domain.

We now review the statement of the whole process. First, impose two constraints for conservation of density and momentum; then define the discrete inertial force.

However, the following expression appears to treat a symbol as a "variable":  $(\sum_{\alpha=0}^q (\vec{e}_\alpha(q, t) - \vec{e}_\alpha(q - 1, t - 1)))$  which is not exactly the momentum loss. The author then uses the true constraint to define the inertial force and maps that constraint to a velocity-space discretized force field.

The specific issues are:

1. The definition of any force (including a velocity-discrete force field) should take a form like

$$F^i(q, t) = \frac{1}{\Delta t} \sum_{\alpha=1}^q N_\alpha(q, t) (\vec{e}_\alpha(q, t) - \vec{e}_\alpha(q - 1, t - 1)) \cdot \hat{g}^i(q, t), \quad (1.14)$$

where  $\hat{g}^i = \frac{\vec{g}^i}{|\vec{g}^i|}$  is the unit vector in the  $i$ -th coordinate direction. This form uses a time difference (division by  $\Delta t$ ) and projects onto the unit vector to obtain the component. The author's original expression omits the time scaling and the projection, which complicates interpretation.

2. The second issue concerns the use of  $\vec{g}^i$  in equation (1.13). If  $\vec{g}^i$  is intended to extract a component, it should be the unit vector  $\hat{g}^i$ . Multiplying by the magnitude  $|\vec{g}^i|$  changes the scaling and can remove the proper coordinate-transformation property of the discrete force field. If a Jacobian or metric factor is required, it should be introduced explicitly and justified.
